As cancer treatment demand outpaces the capacity of ambulatory infusion centers, clinicians are challenged to provide timely, cost-effective, safe, and patient-centered care. Reduction in patient wait times can help address these challenges through more efficient care delivery. To reduce patient waiting times and operating hours, we developed a mathematical optimization model and easy to implement heuristics to generate patient appointment times at an infusion center. Our models explicitly considered the uncertainty of patient infusion times. We also created a detailed discrete event simulation model to evaluate the performance of the new patient appointment schedules. We observe that scheduling patients with longer infusion times earlier in the day results in shorter patient waiting times and total length of day of operations.

**ABSTRACT**

Computer simulation is used to recreate a simple version of the operation of an infusion pod on a regular weekday at the University of Michigan Health System outpatient infusion center

**METHODS**

- 60+ hours of student observations
- 37,000 records of patient visits were reviewed from 3 different electronic health records
- Integration of patient visit data

**COMPUTER SIMULATION**

- Observation & Data
- Patient Flow Mapping
- Simulation Model
- Optimization Model
- Output
- Analysis

- Patient and process flow were mapped after observations in the reception area, infusion area, oncology clinic, and pharmacy and
- Validated through expert opinion

**OPTIMIZATION MODEL**

- Goal: Generate appointment schedules that reduce patient waiting times and total length of day of operations
- Results: Appointment times, Patient sequence, Patient-chair assignment
- Type of model: Stochastic
  - The use of a stochastic model allows us to account for the uncertainty associated with the duration of patients’ infusion and the effect on the length of day and wait times
  - Each scenario in the model assigns a particular infusion time to each patient
  - The variability in each patient’s infusion time is accounted for by solving the model for multiple scenarios

**RESULTS**

- Appointment schedules generated by the optimization model result in reduced patient wait times and total hours of operation compared to the ones generated by the Baseline schedule, and the LPT and SPT heuristics
- Initial results demonstrate a 70% reduction in patient wait times using the appointment schedules generated by the optimization model

**CONCLUSIONS**

- The effect of implementing different patient appointment schedules at an infusion center can be approximated by a mathematical optimization model
- Results of computer simulation suggest that scheduling patients with longer infusion times earlier in the day results in reduced patient wait times and total length of day

**FUTURE RESEARCH**

- Faster to solve optimization model generating better appointment schedules
- Development of a heuristic that can be easily implemented by schedulers
- Enhancing simulation model
  - Addition of oncology clinic, increased complexity with additional nurses, chairs and patients
